

Database Applications Examples

- Enterprise Information
- Sales: customers, products, purchases
- Accounting: payments, receipts, assets
- Human Resources: Information about employees, salaries, payroll taxes.
- Manufacturing: management of production, inventory, orders, supply
- Banking and finance

Chapter 1: Introduction

- customer information, accounts, loans, and banking transactions.
- Credit card transactions
- Finance: sales and purchases of financial instruments (e.g., stocks and bonds; storing real-time market data
- Universities: registration, grades

Database System Concepts, 7th Ed.

©Silberschatz, Korth and Sudarshan See www.db-book.com for conditions on re-use

Database Applications Examples (Cont.)

- Airlines: reservations, schedules
- generating monthly bills, maintaining balances on prepaid calling Telecommunication: records of calls, texts, and data usage, cards
- Web-based services
- Online retailers: order tracking, customized recommendations
- Online advertisements
- Document databases
- Navigation systems: For maintaining the locations of varies places of interest along with the exact routes of roads, train systems, buses,

©Silberschatz, Korth and Sudarshan

Purpose of Database Systems

In the early days, database applications were built directly on top of file systems, which leads to:

- Data redundancy and inconsistency: data is stored in multiple file formats resulting induplication of information in different files
- Difficulty in accessing data
- Need to write a new program to carry out each new task
- Data isolation
- Multiple files and formats
- Integrity problems
- Integrity constraints (e.g., account balance > 0) become "buried" in program code rather than being stated explicitly
- Hard to add new constraints or change existing ones

©Silberschatz, Korth and Sudarshan 1.6 Database System Concepts - 7th Edition ©Silberschatz, Korth and Sudarshan 1.5 Database System Concepts - 7th Edition

Purpose of Database Systems (Cont.)

- Atomicity of updates
- Failures may leave database in an inconsistent state with partial updates carried out
- Example: Transfer of funds from one account to another should either complete or not happen at all
- Concurrent access by multiple users
- Concurrent access needed for performance
- Uncontrolled concurrent accesses can lead to inconsistencies
- Ex: Two people reading a balance (say 100) and updating it by withdrawing money (say 50 each) at the same time
- Security problems
- Hard to provide user access to some, but not all, data

Database systems offer solutions to all the above problems

Data Models

- A collection of tools for describing
- Data
- Data relationships Data semantics
 - Data constraints
- Relational model
- Entity-Relationship data model (mainly for database design)
- Object-based data models (Object-oriented and Object-relational)
- Semi-structured data model (XML)
- Other older models:
- Network model
- Hierarchical model

View of Data

An architecture for a database system

Database System Concepts - 7th Edition

©Silberschatz, Korth and Sudarshan

©Silberschatz, Korth and Sudarshan

Physical Data Independence

- Physical Data Independence the ability to modify the physical schema without changing the logical schema
- Applications depend on the logical schema
- components should be well defined so that changes in some parts In general, the interfaces between the various levels and do not seriously influence others.

Instances and Schemas

- Similar to types and variables in programming languages
- Logical Schema the overall logical structure of the database
- customers and accounts in a bank and the relationship between Example: The database consists of information about a set of them
- Analogous to type information of a variable in a program
- Physical schema- the overall physical structure of the database
- Instance the actual content of the database at a particular point in
- Analogous to the value of a variable

Database System Concepts - 7th Edition

1.15

Data Definition Language (DDL)

Specification notation for defining the database schema

char(5), create table instructor (Example:

varchar(20), name

numeric(8,2)) dept_name varchar(20), salary

- DDL compiler generates a set of table templates stored in a data dictionary
- Data dictionary contains metadata (i.e., data about data)
- Database schema
- Integrity constraints
- Primary key (ID uniquely identifies instructors)
- Authorization
- Who can access what

Data Manipulation Language (DML)

- Language for accessing and updating the data organized by the appropriate data model
- DML also known as query language
- Two classes of languages
- Pure used for proving properties about computational power and for optimization
- Relational Algebra
- Tuple relational calculus
- Domain relational calculus
- Commercial used in commercial systems
- SQL is the most widely used commercial language

©Silberschatz, Korth and Sudarshan

SQL Query Language

- SQL query language is nonprocedural. A query takes as input several tables (possibly only one) and always returns a single table.
- Example to find all instructors in Comp. Sci. dept

select name

from instructor

where dept_name = 'Comp. Sci.'

- SQL is NOT a Turing machine equivalent language
 To be able to compute complex functions SQL is usually embedded in
- Application programs generally access databases through one of

some higher-level language

- Language extensions to allow embedded SQL
- Application program interface (e.g., ODBC/JDBC) which allow SQL queries to be sent to a database

Data Manipulation Language (Cont.)

- There are basically two types of data-manipulation language
- **Procedural DML** -- require a user to specify what data are needed and how to get those data.
- Declarative DML -- require a user to specify what data are needed without specifying how to get those data.
- Declarative DMLs are usually easier to learn and use than are procedural DMLs.
- Declarative DMLs are also referred to as non-procedural DMLs
- The portion of a DML that involves information retrieval is called a query language.

Database System Concepts - 7th Edition

Silberschatz, Korth and Sudarshan

Database Access from Application Program

- Non-procedural query languages such as SQL are not as powerful as a universal Turing machine.
- SQL does not support actions such as input from users, output to displays, or communication over the network.
- Such computations and actions must be written in a host language, such as C/C++, Java or Python, with embedded SQL queries that access the data in the database.
- Application programs -- are programs that are used to interact with the database in this fashion.

Database Design

The process of designing the general structure of the database:

design requires that we find a "good" collection of relation schemas. Logical Design – Deciding on the database schema. Database

The functional components of a database system can be divided into

The transaction management component.

The query processor component,

The storage manager,

A database system is partitioned into modules that deal with each of

he responsibilities of the overall system.

Database Engine

- Business decision What attributes should we record in the database?
 - and how should the attributes be distributed among the various relation Computer Science decision - What relation schemas should we have schemas?
 - Physical Design Deciding on the physical layout of the database

©Silberschatz, Korth and Sudarshan

Storage Manager

Database System Concepts - 7th Edition

- data stored in the database and the application programs and queries A program module that provides the interface between the low-level submitted to the system.
- The storage manager is responsible to the following tasks:
- Interaction with the OS file manager
- Efficient storing, retrieving and updating of data\
- The storage manager components include:
- Authorization and integrity manager
- Transaction manager
 - File manager
- **Buffer manager**

Database System Concepts - 7th Edition

©Silberschatz, Korth and Sudarshan

The storage manager implements several data structures as part of

Storage Manager (Cont.)

Data files -- store the database itself

the physical system implementation:

- Data dictionary stores metadata about the structure of the database, in particular the schema of the database.
- Indices -- can provide fast access to data items. A database index provides pointers to those data items that hold a particular value.

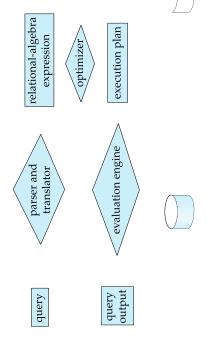

Query Processor

- The query processor components include:
- DDL interpreter -- interprets DDL statements and records the definitions in the data dictionary.
 - DML compiler -- translates DML statements in a query language into an evaluation plan consisting of low-level instructions that the query evaluation engine understands.
- The DML compiler performs query optimization; that is, it picks the lowest cost evaluation plan from among the various alternatives.
- Query evaluation engine -- executes low-level instructions generated by the DML compiler.

Query Processing

- 1. Parsing and translation
- Optimization ۲
- Evaluation

1.27

©Silberschatz, Korth and Sudarshan

Transaction Management

- A transaction is a collection of operations that performs a single logical function in a database application
- Transaction-management component ensures that the database remains in a consistent (correct) state despite system failures (e.g., power failures and operating system crashes) and transaction failures.
- Concurrency-control manager controls the interaction among the concurrent transactions, to ensure the consistency of the database.

Database System Concepts - 7th Edition

Database Architecture

- Centralized databases
- One to a few cores, shared memory
- Client-server,
- One server machine executes work on behalf of multiple client machines. Parallel databases
- Many core shared memory
- Shared disk
- Shared nothing
- Distributed databases
- Geographical distribution
- Schema/data heterogeneity

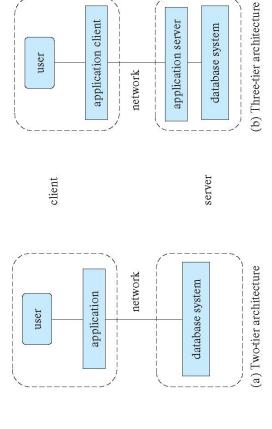

Database Applications

Database applications are usually partitioned into two or three parts

- Two-tier architecture -- the application resides at the client machine, where it invokes database system functionality at the server machine
- Three-tier architecture -- the client machine acts as a front end and does not contain any direct database calls.
- The client end communicates with an application server, usually through a forms interface.
- The application server in turn communicates with a database system to access data.

Two-tier and three-tier architectures

©Silberschatz, Korth and Sudarshan

1.31

Database Users

Database System Concepts - 7th Edition

There are four different types of database-system users

- Naive users unsophisticated users who interact with the system by invoking one of the application programs that have been written previously.
- Application programmers -- are computer professionals who write application programs.
- Sophisticated users -- interact with the system without writing programs
- using a database query language or by
- using tools such as data analysis software.
- Specialized users --write specialized database applications that do not fit into the traditional data-processing framework. For example, CAD, graphic data, audio, video.

Database System Concepts - 7th Edition

©Silberschatz, Korth and Sudarshan

Database Administrator

A person who has central control over the system is called a database administrator (DBA), whose functions are:

- Schema definition
- Storage structure and access-method definition
- Schema and physical-organization modification
- Granting of authorization for data access
- Routine maintenance
- Periodically backing up the database
- Ensuring that enough free disk space is available for normal operations, and upgrading disk space as required
- Monitoring jobs running on the database and ensuring that performance is not degraded by very expensive tasks submitted by some users

©Silberschatz, Korth and Sudarshan 133 Database System Concepts - 7th Edition ©Silberschatz, Korth and Sudarshan 1.32 Database System Concepts - 7th Edition

History of Database Systems

- 1950s and early 1960s:
- Data processing using magnetic tapes for storage
- Tapes provided only sequential access
 - Punched cards for input
- Late 1960s and 1970s:
- Hard disks allowed direct access to data
- Network and hierarchical data models in widespread use
- Ted Codd defines the relational data model
- Would win the ACM Turing Award for this work
- IBM Research begins System R prototype
- UC Berkeley (Michael Stonebraker) begins Ingres prototype
- Oracle releases first commercial relational database
- High-performance (for the era) transaction processing

History of Database Systems (Cont.)

- **2000s**
- Big data storage systems
- Google BigTable, Yahoo PNuts, Amazon,
- "NoSQL" systems.
- Big data analysis: beyond SQL
- Map reduce and friends
- SQL reloaded
- SQL front end to Map Reduce systems
- Massively parallel database systems
- Multi-core main-memory databases

History of Database Systems (Cont.)

- Research relational prototypes evolve into commercial systems
- SQL becomes industrial standard
- Parallel and distributed database systems
- Wisconsin, IBM, Teradata
- Object-oriented database systems
- 1990s:
- Large decision support and data-mining applications
- Large multi-terabyte data warehouses
- Emergence of Web commerce
